3.1 METHOD DESCRIPTION

A hydrologic analysis was carried out to establish the peak discharge-frequency relationships for the study area. The methodology stipulated in the Contract Scope of Work for studying the watershed is contained in the 1992 Flood Control District Hydrologic Design Manual for Maricopa County, Arizona. There are no stream flow nor significant rainfall records available for the White Tanks Wash drainage basin. The only means for calibration of the rainfall-runoff projections, therefore, is by comparison with other methods and studies. The precipitation for the area was obtained from NOAA Atlas 2, Volume VIII isopluvial maps of the area, prepared by the Office of Hydrology, National Weather Service. They were plotted as precipitation depth versus return period on a partial duration series plot. The watershed runoff was studied for both the 100-year 6-hour duration storm using the Flood Control Districts distribution and the 100-year 24-hour duration storm using SCS Type II distribution. Areal reduction, using the Corps of Engineers' Queen Creek method, was applied to the 6-hour storm. NOAA HYDRO-40 was used for the 24 hour calculations. Rainfall losses were calculated using the Green and Ampt equation based on published SCS soil texture data, with surface retention losses and vegetative cover effects accounted for. The S-Graph method was used for developing the unit hydrographs for the entire basin. The method is applicable even for those sub-basins that are less than five square miles in area if they have a time of concentration greater than the duration of the most intense rainfall. Time of concentration was determined using the S-Graph lag equation. Routing was accomplished using normal depth routing, with the general locations for the typical cross sections selected from quadrangle maps and aerial photos but with the dimensions and "n" values determined in the field. The U. S. Army Corps of Engineers, Hydrologic Engineering Center computer program HEC-1, Version 4.0, September 1990 as implemented by Haestad Methods was used to process the data.

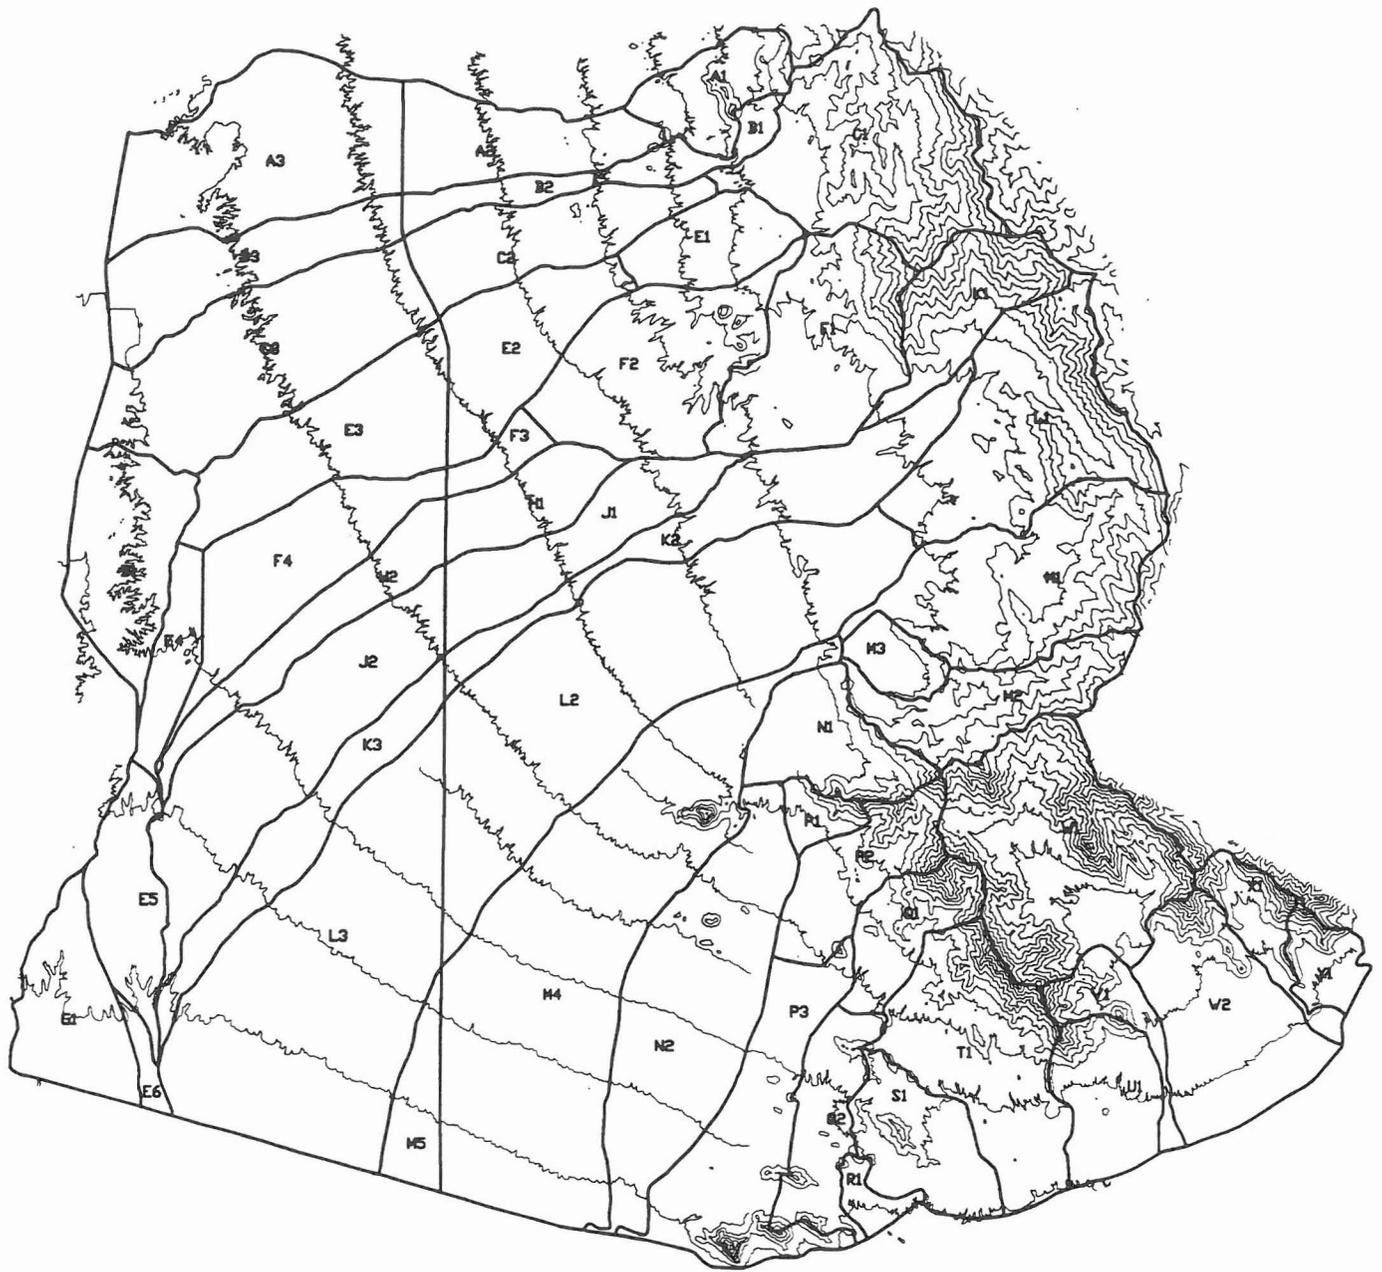

3.2 PARAMETER ESTIMATION

3.2.1 Drainage Area Boundaries

The White Tanks Wash FIS area lies 40 miles west of Phoenix (see Fig. 1, Vicinity Map). The hydrologic study area is 111.5 square miles, bounded on the west by the Hassayampa River; on the north by the Wagner Wash watershed; on the east by the crest of the White Tank Mountains; and on the south by Buckeye Structures #1, 2 and 3 north of highway I-10. The basin is shown on Figure 4, the Study Area Map. The watershed was subdivided into four distinct zones based upon topographic characteristics: the mountains to the east, the piedmont in the eastern low gradient desert area, the stable channel area west of the Parkway, and the small drainages that border the Hassayampa River. All basin boundaries and flow channels were digitized and combined with the digitized quadrangle maps in AutoCad and used to determine areas and lengths for calculations.

The "White Tank Mountains Flood Hazard Maps" from the "Geologic Mapping of Flood Hazards in Maricopa County" (ref 9) were of considerable assistance in determining areas unaffected by flooding. The Geologic Mapping study involved determining the extent of disturbance of desert pavement and small rocks with "desert varnish" on them. By combining topographic relief, soil development and the age of the varnish with mapping of the disturbed varnish area boundaries, it was possible to conclude that certain areas had been undisturbed by stream flow for periods from a thousand to over ten thousand years. These periods greatly exceed the 100 year or less period of engineering interest for flood plain studies and are an excellent indicator of the stability of stream location. The areas so identified can generally be considered permanently flood free for engineering design, planning and flood insurance purposes.

In geological time, any area at the foot of mountains can be considered to be an alluvial fan and subject to movement of the area inundated during floods in a seemingly capricious manner. Engineering flood studies are concerned with more localized areas and much shorter time periods than required for significant geological changes such as tectonic movements. However, if the above information is combined with the hydraulic information, areas can be delineated that have a low risk of inundation in an engineering time frame. If such an area is subject to development, the areas that are now stable and not subject to flooding will probably still be flood free after the developments have passed into antiquity. Development of a storm drainage system and its subsequent maintenance are much more likely to maintain these areas above flood level than to change the conditions and make them flood prone. The County must, however, review the development plans to assure that the floodways are adequately sized, correctly located and properly designed.

SCALE 1" = 10,000 FEET

STUDY AREA

FIGURE 4

The mountain area involves steep, deeply incised drainages in the White Tank Mountains and foothills. Subbasin watershed boundaries are clearly defined laterally, and downstream longitudinal boundaries were selected at the point where the streams emerge from the mountain valleys. Dividing ridges were identified from the contours on the quadrangle maps and refined through study of the stereo aerial photos.

The sub-basins in the low gradient desert piedmont area from the foot of the mountains to either the Parkway or to the Buckeye Structures in the southeast are clearly defined longitudinally but in some areas poorly defined laterally. The quadrangle maps with 20-foot contours were of limited usefulness in this area, as many of the dividing ridges were only about 10-feet high. The "White Tank Mountains Flood Hazard Maps" from the "Geologic Mapping of Flood Hazards in Maricopa County" (ref 9) were used to determine preliminary boundaries. The aerial photos were studied extensively in this area to establish reliable long-term basin divides and to contain any distributary flow areas. This office work was augmented by a field trip to each location that had questionable usefulness as a divide or was a possible distributary flow area. Eight possible distributary flow areas were identified in the piedmont area and are discussed in detail in Section 3.4, Special Problems/Solutions. Initially the sub-basin size was to be limited to six square miles, but this limit was adjusted when it became apparent that the physical basins had to be wider than anticipated. As a result of this process, four sub-basins (M4, N2, L2 and L3) were delineated that were larger than the desired size. In the first two cases, narrower sub-basins would have resulted in arbitrary borders that would have been subject to flow crossing from one sub-basin to the next. Problems within a 100 year engineering time frame could have included inundation of the dividing ridge during large peak flows, distributary flow areas or channel migration. Sub-basin L3 is downstream of the Parkway but for consistency it's boundaries were selected in conjunction with L2. None of these four sub-basins directly influence the hydraulic study area of White Tanks Wash. Selection of boundaries for the other sub-basins in this area were developed in conjunction with the upstream and downstream sub-basins to provide consistent drainage basin boundaries from mountain top to mouth.

The delineated drainage channels are all in the stable stream area downstream and west of the Parkway. The larger sediments from major storms has been deposited upstream in the low gradient piedmont area. Channel shifts and flow changes in this area are almost always the result of distributary flow upstream not local changes. The area was studied in detail by Field and Pearthree and reported upon in Geologic Mapping of Flood Hazards in Maricopa County (ref 9). Their method of determining that surface rocks have not been disturbed in recent geologic time based upon the development of desert varnish on the exposed surface has provided scientific support to normal field observation. Observations in the field, comparison with the results of the Geologic study and review by Professor Laursen all indicate that these basins have remained static for centuries and will probably remain static for many more centuries.

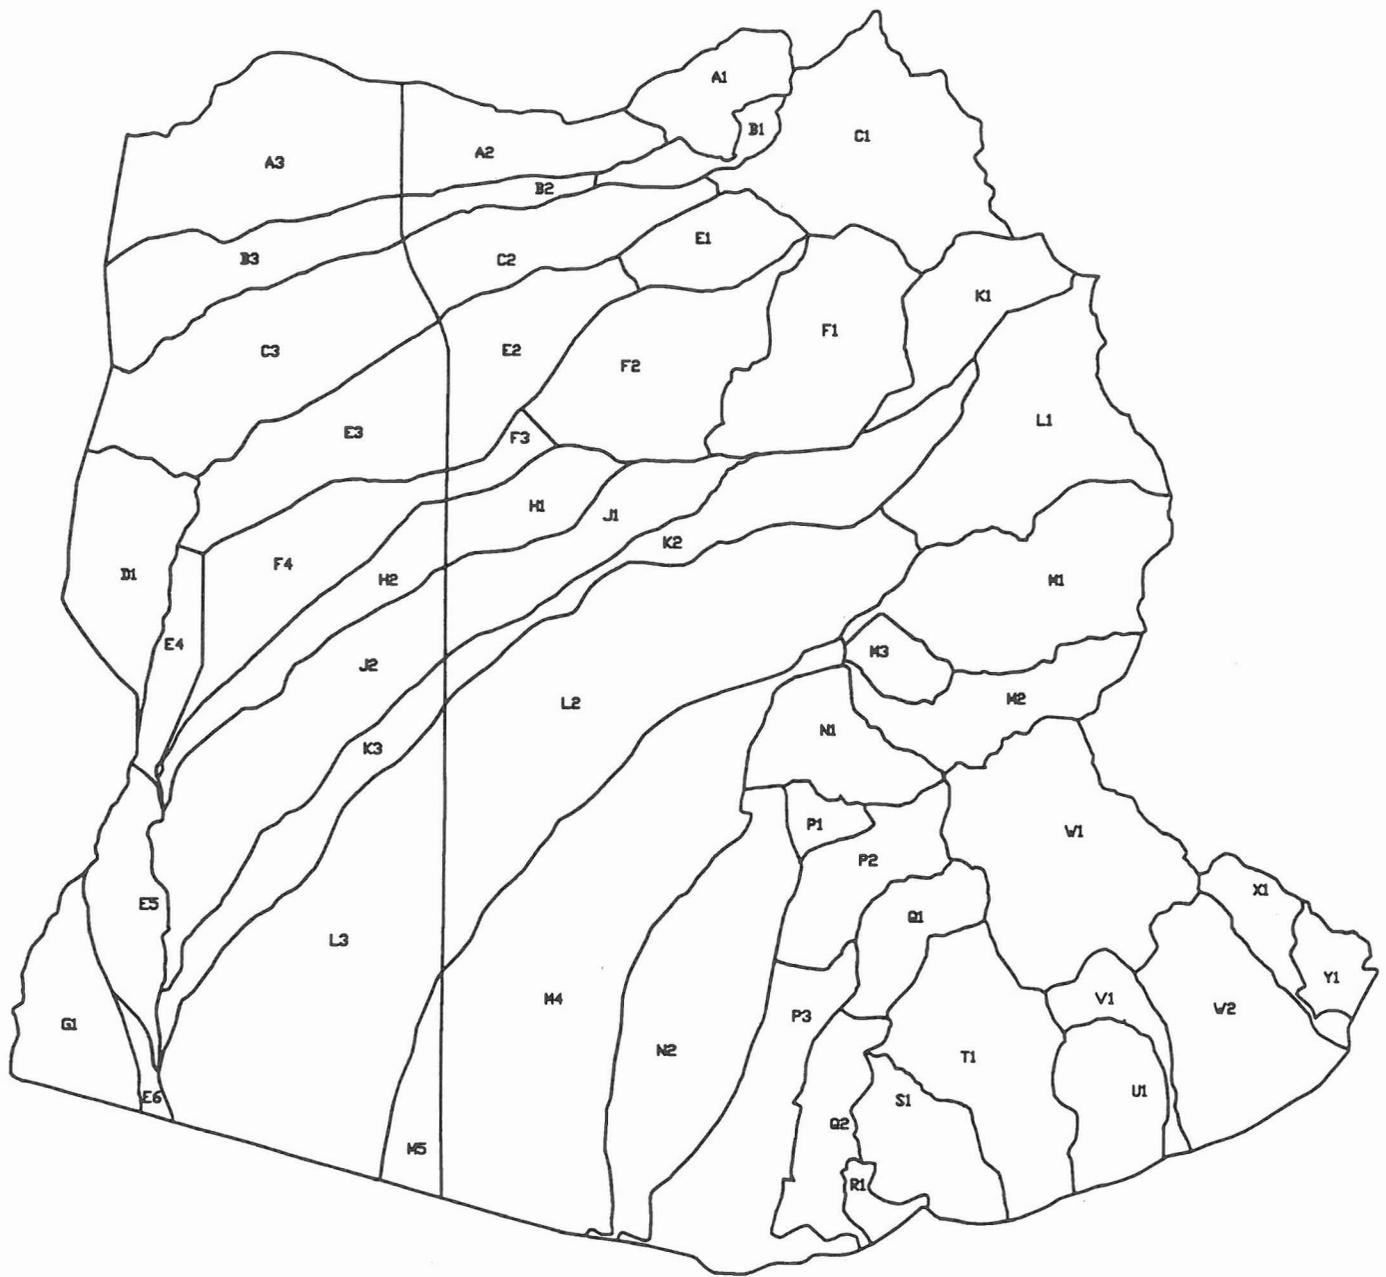

The construction of the Parkway with its culvert crossings has further stabilized and defined the flow coming into these channels in both location and maximum quantity. The paved surface of the Parkway is unlikely to erode and will certainly not remain eroded for long in the very unlikely event that the Parkway is overtopped. The culverts and roadside ditches have sufficient cross-sectional area to convey and divert all of the 100 year flow from individual channels under or downgrade along the Parkway without overtopping the roadway. The maximum discharge through any culvert is limited by inlet control under approximately one to three feet of surcharge. Therefore the location of the streams is dictated by the culvert location and the maximum flow quantity by the culvert size. The stream reaches in this area are more than three miles from the primary source of sediment at the base of the mountains. Most of the large sediment has been deposited far upstream in the distributary flow areas during small storms and only moved downstream towards the Parkway by very large storms. The upstream flood flow during large floods will be sediment carrying flow at a much higher velocity than in the backwater pond above the culvert. During storms large enough to create a significant backwater (generally larger than a 10 year event), the streams drop a high percentage of their sand and gravel sediment upstream of the Sun Valley Parkway in the backwater of the culverts. If the culvert capacity is not exceeded, the flow velocity will increase downstream to approximately the same range as it was above the culvert because the channel slopes are similar. This flow will be transporting less sediment than it can carry at that velocity. The result is commonly described as clear water scour in the stream bed downstream of the Parkway. In order to reach a stable sediment transport condition, the stream will erode in this area. The resulting incising and degradation of the bed downstream of the culvert will continue until a new equilibrium is reached in the area. The channels, and therefore the sub-basin boundaries, will remain essentially static and predicable in location with only typical riverine side cutting of the banks occurring.

Each of the sub-basins in the stable stream area could be divided one or more times longitudinally. Continuing the basin boundaries upstream for the inflow basins in the piedmont upstream of the Parkway would involve distributary flow areas that would make allocation of the flow problematical. During very large floods, some of the flow reaching culverts near the north edge of each basin may exceed the culvert's capacity and flow south along the east edge of the Parkway. When the flow reaches the next culvert, it will combine and either flow through the culvert or continue the process to the south. The interconnection along the Parkway of the streams between subbasins was computed and incorporated into the study. The only occurrence of this for a 100-year event was between subbasin F and H. For study purposes, this diversion produces the same result as if flow had been diverted from subbasin F to G in the distributary flow area upstream. In most cases within a subbasin where flow may divert along the Parkway, the flow from two or more culverts combines a short distance to the west of the Parkway and was not therefore separately calculated.

The basins that drain directly into the Hassayampa River, rather than into the White Tanks Wash, were included in the hydrologic study to provide continuous hydrology coverage with adjoining flood studies. Sub-drainages A through C on the north edge of the study are fully developed basins that drain westward from the mountains, across the piedmont and Parkway, to the river. Sub-basins D1 and G1 are small areas that include several very small, short ephemeral streams that drain the eastern river bank and flow west into the river and were not separately modeled. Basins M through Y drain the southeastern portion of the hydrologic study area into the Buckeye Floodwater Retarding Structures separate from the White Tanks Wash.

Considerable effort was expended to delineate basins that do not have distributary flow areas that would have split or cross-over flows into adjacent basins. The USGS quadrangle maps were used to determine preliminary basin boundaries at every significant ridge line, even if only of minor elevation difference. During the study of basin boundaries, comparisons were made to previous drainage studies and most importantly to the results of the Flood Hazards of Distributary-Flow Areas in Southwestern Arizona (ref 67) and to Geologic Mapping of Flood Hazards in Maricopa County (ref 9). Each of the identified ridges was then studied on the aerial photos with a large stereoscope for current bank height and split flow evidence. Finally, each questionable site was visited in the field on January 27, 28 and 29, 1992 to determine the reliability of the ridge as a true long-term basin boundary. The effects of the eight identified distributary flow areas are discussed in Section 3.4. The resulting basin boundaries selected are, in a few cases, larger than the most desirable, but they are clearly delineated basins without split flow between basins.

The watershed was broken into 49 sub-basins averaging 2-¼ square miles in area. There are 23 mountain, 13 piedmont and 13 stable sub-basins; all classified as Sonoran desert. Sub-basin M5 and southern L3 are largely medium-density residential with subdivision roads and utilities in place. The middle portion of W2 has been subdivided but only a couple of residences have been constructed to date. A few scattered residences exist in sub-basins E4, J2, K3 and P3. There are five power transmission lines across the area, communications relays on several of the mountain tops and numerous old mine claims and explorations in the foothills. Primitive gravel and dirt roads exist for these facilities. The Sun Valley Parkway, a paved, divided highway, splits the area from north to south. The balance of the area is essentially rural and undeveloped, but large areas are in private ownership and were slated for development prior to the recent real estate downturn. There have been only minor attempts at agriculture in the area, except for range grazing during the winter months.

DRAINAGE BASINS

FIGURE 3

3.2.2 Physical Parameters

Physical parameters were determined in accordance with the Maricopa County Hydrologic Design Manual (ref 29). Detailed explanations of the procedures are contained therein, and only those procedures that required a choice of method that varied from the standard methods or that were conducted in a special manner are explained below. Tables are included with results at the end of this section.

Green and Ampt Soils Parameters

The Generalized Hydrologic Soils Map for Arizona published by the SCS in March 1959 classifies the mountainous portion of the area as hydrologic soil group D and the balance of the area as group C, indicating that a relatively high runoff ratio can be expected. Soil Map Unit classifications used in this report were obtained from the SCS Soil Surveys of Central Maricopa County and Aguila-Carefree Area (ref 59 & 60). These maps show the majority of the piedmont area as hydrologic soil group B. The soil maps were digitized and coordinate matched to the basin map in vector format. During this process, several discrepancies were found in the soil maps, particularly at the boundary between the two maps. These were resolved through discussions with the local soil conservation office and the maps revised accordingly. All of these changes were minor except for two SCS labeling errors. Areas of the soil types in each basin were then determined directly from the combined computer maps, with the accuracy limited only by the digitizing accuracy and original map accuracy. The values for the area of each soil type in the sub-basin, slope and vegetative cover were entered into the FCDMC program S-GRAPH.WK1, which then determined the values for XKSAT and percentage of rock in each soil type from a FCDMC look-up table based on SCS soil survey data. The program also requires the input of land use and vegetative cover to modify the output values for HEC-1 input. The program uses these values to compute a composite, areally adjusted XKSAT for the sub-basin and values for DTHETA, PSIF and RTIMP. For storms where the infiltration rate is less than the rainfall intensity, the Green and Ampt equation is $f = K(1 + \psi\Theta/F)$, where f = infiltration rate, K = XKSAT or the steady state hydraulic conductivity at natural saturation in the wetted zone, ψ = PSIF or the average wetting front capillary suction, Θ = DTHETA or the volumetric soil moisture deficit at the start of rainfall, and F = the depth of rainfall that has infiltrated into the soil since the beginning of rainfall. Results of the S-GRAPH calculations are presented in tabular form in Section 3.2.2.1. The MCUHP2 (Maricopa County Unit Hydrograph Program 2 for S-Graph) dated 12/16/91 developed by the FCDMC was used to build the data for the HEC-1 input file for the S- Graph option. The output file includes the selected rainfall distribution, unit graph selection and soil parameters.

Vegetation coverage on undeveloped desert areas was determined by first physically performing several transects at different times of the year in the field to provide a basic reference. This was used to evaluate a previously developed equation that converts SCS data for dry pounds per acre of rangeland total plant production in a normal year to percent of vegetative cover. Use of this equation removes the bias inherent in doing the work during a wet, highly productive or dry, low productive period and provides a source of information that is not dependent upon the engineering observer nor the particular time or place the transects are taken. The equation is simply 0.6 times the square root of the dry pounds per acre. The equation is valid from no production equalling zero cover to 28,000 pounds per acre equalling 100 percent coverage, which is equivalent to a very heavy production of alfalfa. Use of this concept and equation also provides a correlation between the very sparsely covered desert terrain in Maricopa County and the very dense coverage of coastal rain forests. If an area of forest or alfalfa with obviously a maximum of 100 percent coverage has more than 10 times the plant cover than the desert does, the desert shouldn't be considered 30 percent covered. The 10 to 15 percent vegetative cover that resulted for the report area is a more reasonable average estimate.

Parameters for Reach Routing

The normal depth channel option in HEC-1 was used to route the flood hydrographs. The relevant input data is presented in Section 3.2.2.2. Each reach was identified on the quadrangle maps and the stream digitized. The elevation at each end of the reach was determined from the contour mapping. The length of the reach was obtained directly from the length of the stream polyline in the vectorized drawing. Centroids of each sub-basin were determined using scale models and transferred to the stream point opposite it. The stream in this area was studied on the topographic maps and in stereo from the aerial photos to determine the sub-reach near the centroid that was most typical of the entire reach. A peak 100-year flow was determined from an envelope curve equation and tabulated for field use. A quick solution of Manning's equation on a palm-top computer in the field provided assurance that the cross section information obtained was wide enough to define the channel and the over-bank "n" values were selected for the right areas.

Initially, each site was to be located using aerial photos alone. In the low gradient terrain east of the Parkway, streams had sections that were very similar in appearance to the next stream. Either considerable time had to be spent tracking your position on the photos or mistakes were certain to occur. This was unacceptable, so a small portable Geodetic Positioning System (GPS) unit was obtained. Each of the typical reaches were identified by latitude and longitude from the aerial photos and the GPS receiver was used to guide us accurately and directly to each site in the field. The entire process was checked by confirming the location with the aerial photos. Several hundred feet of each channel were walked in each case, and a typical or average cross section was selected and measured. The "n" values were determined for the channel and over-bank area using the USGS procedure in "estimating Manning's Roughness Coefficients" (ref 62) and a picture was taken at each site (see Section 3.2.2.3).

Typically, these washes have a small low flow channel with a sandy bed that is bordered by relatively heavy brush. The channel bed forms are dependant upon channel alignment, encroaching trees or large brush, and the size and slope of the falling limb of the hydrograph of the last storm. After several small storms, the beds are typically flat and uniformly graded sand or small gravel. After a large short-duration storm, the beds have numerous dunes, local scour at obstructions, restrictions and curves. The underlying bed material varies from sand to large cobbles with a high permeability over a calcareous sandy to gravelly clay loam with varying degrees of cementation that has only a moderate to low permeability. The brush along the edges of the low flow channel is sometimes so dense and thorny that it is impossible to pass through it without a detour or a machete. In addition, the banks are often irregular in alignment and rough in texture. Determination of realistic "n" values for these channel areas requires considerable judgement and experience. The method for determining "n" values using a base value with adjustment factors as outlined in reference 63 was used throughout this project. The recommended values and pictures in the reference were also related to past experience and other sources. A field trip with Russ Cluff, the most "n" value experienced member of the FCDMC staff, was especially helpful. In addition, a few HEC-2 test calculations were run using separate "n" values for the banks and center of the low flow channel and compared with composite "n" values to provide a guide for determining composite values. The "n" values for the over-bank areas were relatively easy to determine since they were quite homogeneous in each section of the reach. Over-bank vegetation is similar, but slightly heavier than the average vegetation for the area. The low flow channels often decrease in width as they progress downstream in the piedmont zone because channel infiltration during small, frequent storms depletes the runoff. The bed material typically has a high initial infiltration rate that, within the storage capacity of the material, will absorb much of the initial storm flows in the channel. The lower infiltration rate and capacity of the underlying parent material sets a limit on total infiltration rate and capacity. As a result, the large short duration peaks of the typical 100 year intense desert storms are reduced very little. Total outflow volume is however reduced by the infiltration volume. Field data sheets are in Section 3.2.2.4.

Transmission Losses

Transmission losses do not substantially reduce the 100-year peak flow and were not incorporated into the HEC-1 calculations for several reasons. There are insufficient available stream flow and precipitation data on which to base a transmission loss calibration. This study does not require that a volume of flow during the storm be determined, only the peak flows. During a 100-year event, the effect of infiltration in short stream channels normally has little effect on the peak flow. Percolation tests and falling head permeameter tests in similar streams indicate substantially higher (5 to 20 times) infiltration rates in the sand and gravel channels than in the overbank areas. Considerable care needs to be used when applying this information. In a major storm, the channel becomes saturated well before the hydrograph peak reaches any point. Several of the stream beds investigated in this study have caliche bases from 0 to 3 feet below the thalweg. Unless done with very large volumes of water, percolation tests merely indicate that the bed material is porous for a limited depth. In the streams with a caliche or rock base, the infiltrated water flows underground and often surfaces again when the base approaches the stream bed. Transmission losses are occasionally used as a means of correcting for other poorly determined input factors. Initial infiltration in the stream channel is at least partially accounted for in the Green and Ampt infiltration losses for each entire sub-basin. A simple calculation indicates that the effect that channel infiltration would have on the 100-year peak flow is less than 0.5 percent of the flow, or .01 foot elevation. Although this is insignificant for a 100-year flood event, the infiltration becomes very significant for small floods, such as annual recurrence events, and cannot be ignored.

Number of Routing Steps

Selection of the number of routing steps (NSTPS) using normal depth routing calculations is quite critical. The value for NSTPS is given in the HEC-1 manual and in Reference 37 and in the HEC manual as equal to the reach length divided by the average velocity of the flood wave as determined by the Manning formula divided by the computational time interval (NMIN). An approximate NSTPS within each reach was first calculated with Manning's formula using the field data for cross section and "n" values combined with the map values for slope and length. The NMIN value of 5 minutes was selected to be equal to or less than the shortest lag time for the watershed. An initial NSTPS time was calculated and used in a HEC-1 run. Some references indicate that HEC-1 will select the optimal value for NSTPS if left blank. However the program limits this selection to values between 1 and 10. A test of the automatic feature indicated that for the short NSTPS of 5 minutes used in these project, the reduction of peak discharge during routing was too large. A spreadsheet was developed for this computation and then solved in iterative computations using the routed flow quantity from HEC-1 for the input for each iteration. The system is convergent within the values for whole number steps. The final iteration values for both the 6 and 24 hour storms are tabulated on the following pages.

NOTES:

1. This table represents identified problems with soil map units and XKSAT values at boundaries between soil maps in the project area. Soils shown should have the same class, %R and XKSAT north and south of the boundary.
2. In addition to the above, 4 lines were found incorrectly dividing single map units.
2. The last problem in the table has been resolved through a phone call with the SCS. The designation of 96 is in error on SCS map 43 and should be 99 on both maps. The SCS agreed that the four lines should be removed.
4. Based on discussions with FCD staff, we will use the soil classifications as shown on each map and the XKSAT values in the MCUHP2 program.

EXPLANATIONS AND COMMENTS FOR PRECEEDING TABLES

ITEM	UNIT	EQUATIONS OR SOURCE
------	------	---------------------

WATERSHED SGRAPH AND INPUT DATA

ELEV MAX	ft	max elev in subbasin from contour map
ELEV MIN	ft	elev at subbasin outlet from contour map
ELEV DIFF	ft	computed elev difference = elev max - elev min
LENGTH	ft	digitized length of longest water course in basin
LGTH>CENTROID	ft	stream length from outlet to opposite the centroid
SLOPE	'/mi	computed drainage slope = elev diff / length
AREA	sm	area of digitized basin from Autocad
AREA	ac	computed area in acres = area * 640
S-Graph		MTN for upper basins, VAL for others
Kn		selected using similar basin comparisons
LAG	hr	computed using S-LAG program

SUBBASIN SOIL DATA

SOIL GRP A	#	SCS soil survey map
AREA	sm	from Autocad digitized subbasin
XKSAT		soil table for AGUILA & CENTRAL
ROCK OUTCROP	%	soil table for AGUILA & CENTRAL

UNIT HYDROGRAPH SUMMARY

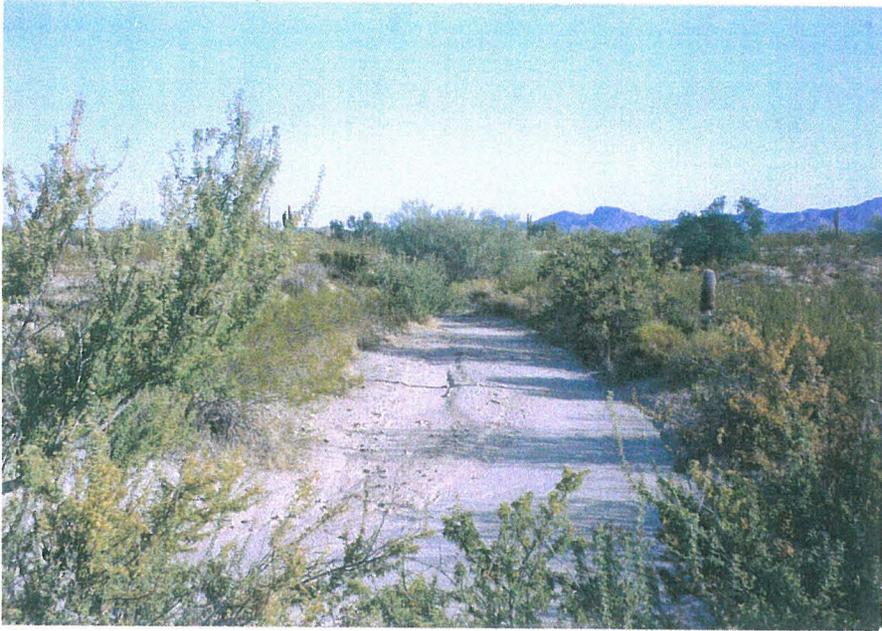

AREA TOT	sm	sum of soil areas = total area
DESERT AREA	sm	from topo map DRY IA= .15 to .35 by slope
VEG COVER	%	weighted %
URBAN AREA	sm	from zoning map DRY IA= .25
VEG COVER	%	estimated %
V.L.D.R AREA	sm	from zoning map NORMAL IA= .30 IMP= 15%
VEG COVER	%	estimated %
AREA VEG COVER	%	weighted %
XKSAT	"/hr	partial sum of soilarea*log(xksat)
XKSAT ROUNDED	"/hr	weighted XKSAT= 10 ^ sum of subarea/area*log(XKSAT)
XKSAT ADJ	"/hr	Rounded to 2 places to match FCD
PSIF	"	adjusted for vegetative cover
DTHETA	"	lookup table then calculated by SGRAPH formula
IA	"	lookup; SGph calc; wgt by use %; dry= .35, norm= .25
RTIMP	%	weighted (desert= .15-.35 by slope; open= .25; VLDR=.3)

3.2.3 Statistical Parameters

The Flood Control District of Maricopa County has expended an extensive amount of effort to determine the statistical basis on which to compute flood studies. The results of those studies from their own efforts; the State of Alaska; the Federal government agencies, particularly the USCE, SCS and FEMA; and consulting engineers have been incorporated into the Hydrologic Design Manual (ref 29) and are used in this report.

3.2.4 Precipitation

This study is based on the 100-year storm recurrence interval. Both the 6- and 24-hour duration storms have been studied to determine the maximum peak outflow. The 6-hour storm uses a distribution developed by the FCDMC, based on the Corps of Engineer's Queen Creek areal reduction. The FCDMC program MCUHP2 was used to produce the input for HEC-1. Based on the basin area, the program interpolates between the closest two of six rainfall distributions.

The 24-hour storm uses an SCS Type II distribution and NOAA Hydro-40 areal reduction calculated in HEC-1.

For both storms, the point precipitation values were determined from the set of isopluvial maps in the Design Manual (extracted from NOAA Atlas 2, Vol VIII, Ref 62) and plotted on a partial duration series plot to obtain the final values of 4.20 inches for the 24-hour storm, and 3.24 inches for the 6-hour.

The total project area at 111.5 square miles is only slightly larger than the 100-square mile upper limit for local (6-hour) storms and well below the established minimum for major storms (24-hour). When the basin size is reduced to the 30 square miles of the White Tanks Wash, it is clearly within the size for the local storm. It was expected, therefore, that the controlling storm for this report would be the 6-hour duration storm. The results, however clearly indicated that the 24 hour SCS storm should be used as the design storm.

An analysis of the hyetographs and HEC-1 outputs for both storms confirms that this is true for all basins and combined basins. The rainfall unit hyetograph data for this project is plotted on the following pages as cumulative "S" curves and then as incremental intensity curves. It is apparent from the graphs that the 24-hour storm is more intense than the 6-hr. The maximum slope on the "S" curve, which is directly proportional to the intensity, for the 24-hour curve is steeper than the 6-hour. The unit intensity curve provides an even more graphic illustration with the maximum 15 minute unit intensity of 0.276 versus 0.152 for the 6-hour storm. In addition, the point rainfall of 3.55" for the 24-hour storm is also larger than the 6-hour. When the maximum incremental rainfalls of 0.28 and 0.16 for the 15 minute interval are multiplied by the point rainfall, the maximum 15 minute rainfall for the total basin is 1.00" and 0.41" for the 24-hour and 6-hour storms respectively.

HEC-1 transforms rainfall excess from the unit rainfall hyetograph to a subbasin hyetograph by applying the areal reduction factor to the point rainfall and then essentially multiplying this reduced subbasin average rainfall rate by each ordinate in the unit hyetograph. The program adjusts the rainfall values for the infiltration and other losses. These losses essentially subtract identical intensities (not volumes) from the different 100 year storms. It then transforms the rainfall excess to subbasin outflow using the following formula:

$$Q(i) = \sum_{j=1}^i U(j) \times x(i-j+1)$$

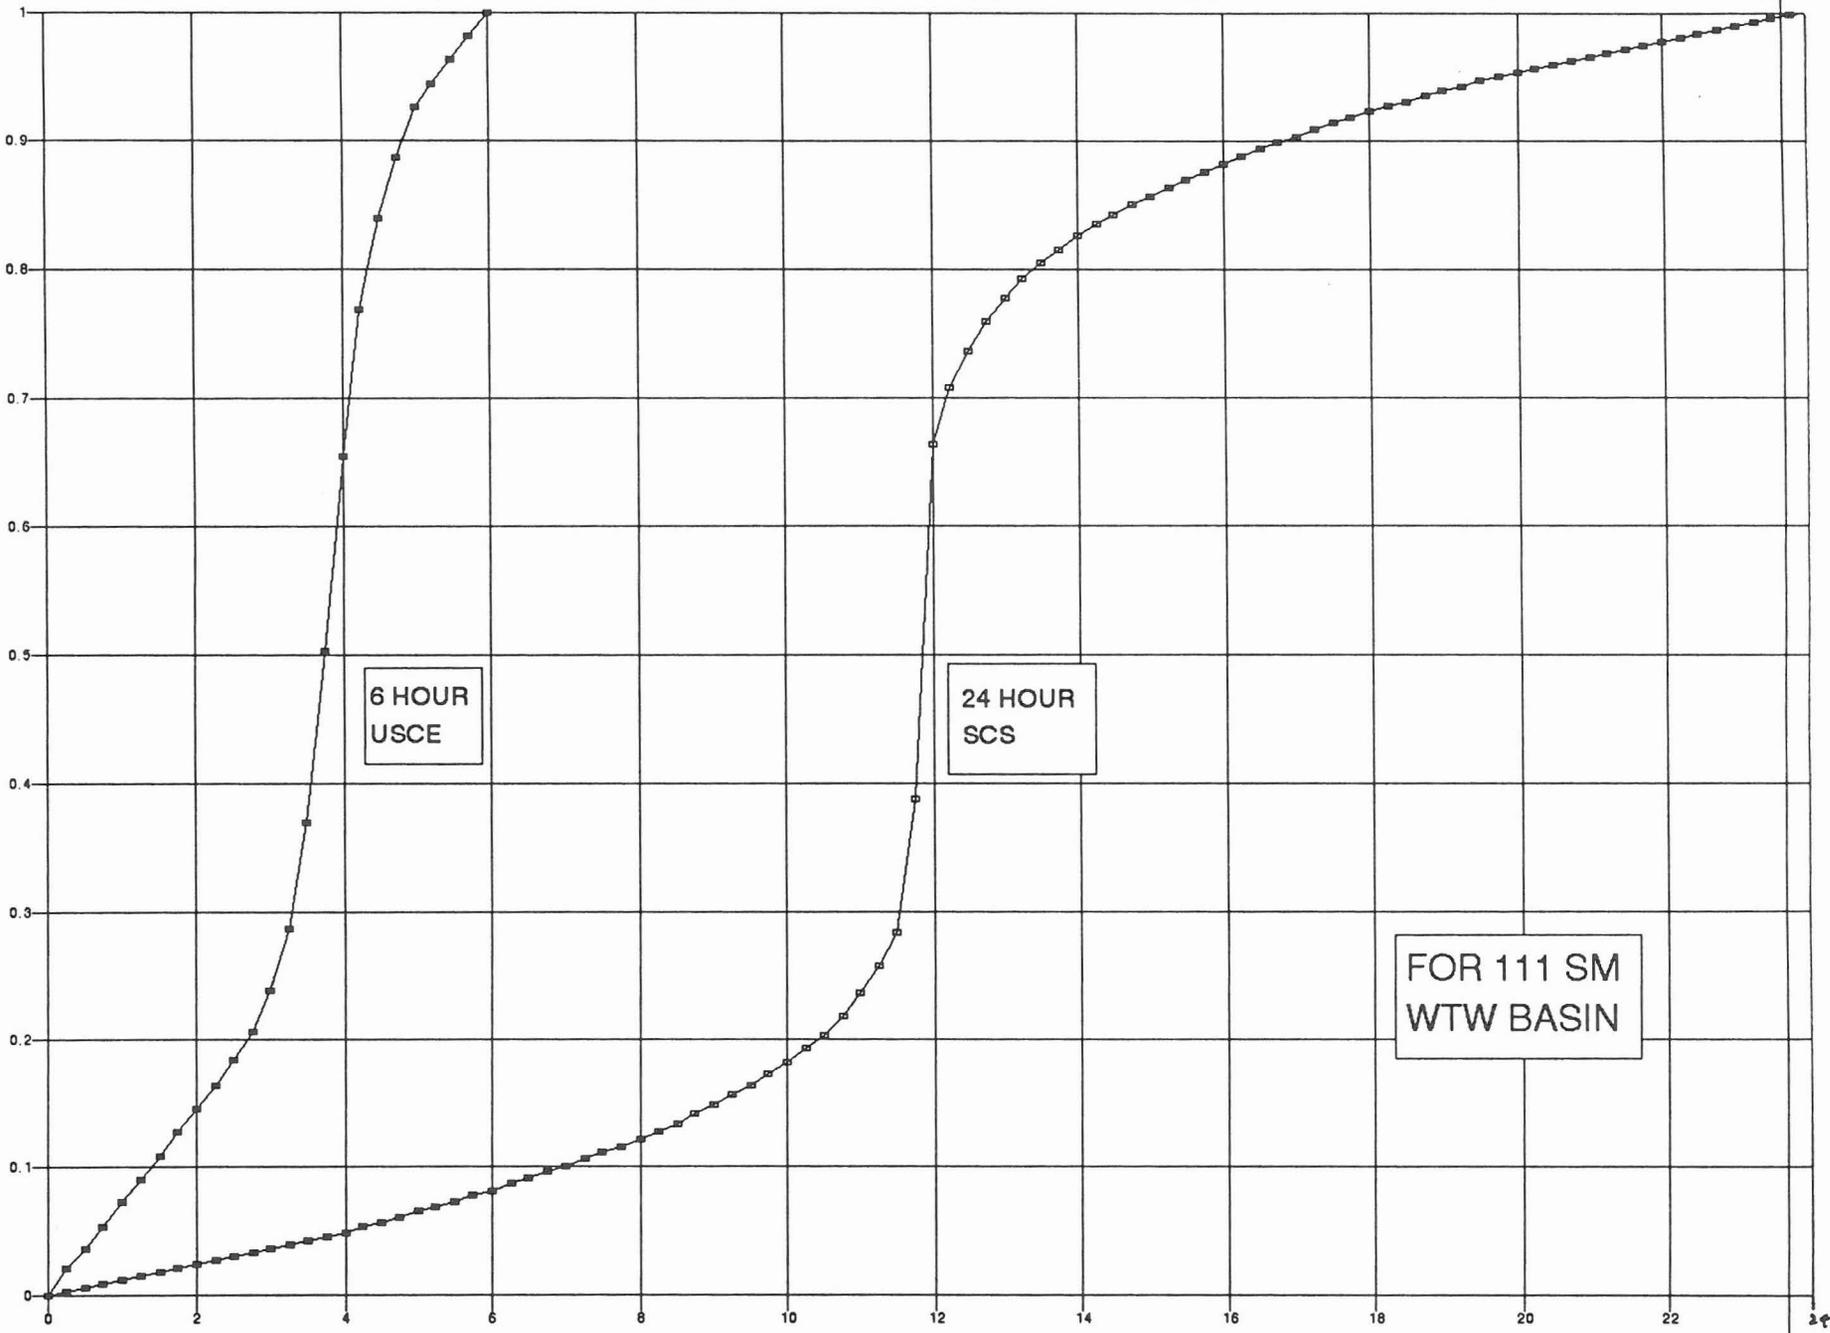

$Q(i)$ = basin outflow at end of computation interval i

$U(j)$ = j th ordinate of the unit hydrograph

$x(i)$ = average rainfall excess for computation interval i

The 24 hour storm produces larger runoff than the 6-hour storm in all basins and is used for all design in this project to provide a conservative design.

3.2.5 Gage Data

The FCDMC has compiled the gage records for Maricopa County. A review of those records indicates that there are no stream flow gages in the project area. The FCDMC has two rainfall gages in the project area: number 5430 at the top of the White Tank Mountains, which was installed on May 15, 1980; and number 5200, referred to as The Hassayampa and I-10 gage, near the outlet structure for Buckeye Structure Number 1, installed July 26, 1983. Neither the period of record nor the number of these gages is sufficient to justify any adjustment to the Maricopa County Isopluvial Maps derived from the NOAA Atlas 2, Volume VIII used in the Hydrologic Design Manual for Maricopa County. There is also a water surface level indicator installed near the outlet of each of the three Buckeye Structures. These would be useful for a calibration check on total flow into the Structures, but not for determining peak flows in individual streams. It is anticipated that a runoff-flood warning gage will be installed next year that will provide information that will permit some calibration of the data in this report in the future.

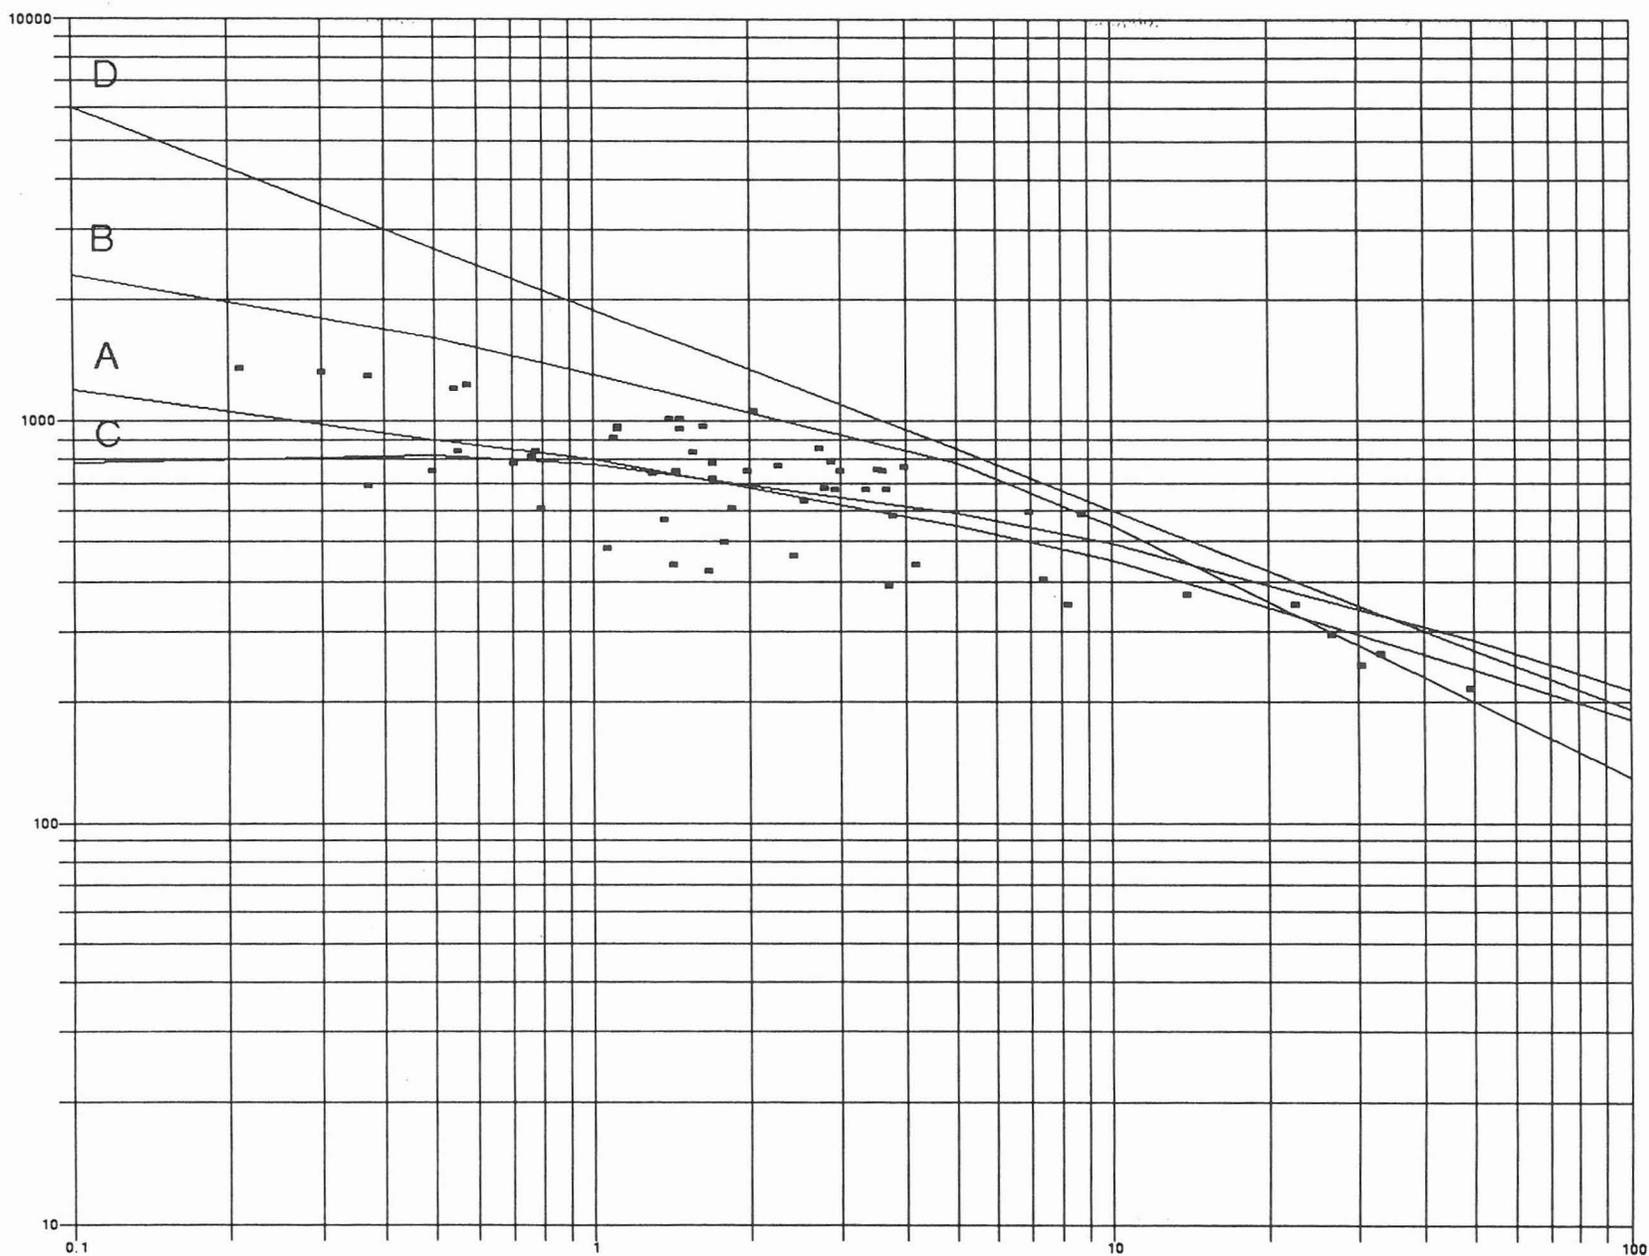

The nearest stream flow gage in a stream with similar watershed characteristics is USGS gage number 09512200 Salt River Tributary in South Mountain Park at Phoenix, Arizona (ref 65). The USGS estimate for the magnitude of the 100-year recurrence interval (1% exceedance probability) instantaneous peak flow is 3220 cfs. There are only 29 years of record at this site (1961-89) and therefore the reliability of the 100 year magnitude discharge is uncertain (25% certainty) and potential errors are large. The discharge per square mile of drainage basin is 1830 cfs per square mile, whereas the highest discharges per square mile for this study were just over 1300 cfs per square mile. This value should be compared to the White Tanks study area with considerable caution and judgement because only the mountainous zone is involved at South Mountain. The piedmont and incised areas are not represented. A different orientation to the southwestly to northeastly prevailing storm track is of significant importance. The South Mountain watershed is on the north slope whereas the White Tanks area is on the southwest slope. The South Mountain basin therefore is not only on the leeward side of the mountain, but also on the shaded north side with different vegetation. The typical cyclic nature of weather and runoff in southern Arizona is graphically demonstrated on this stream with periods of 3.6 and 2.4 years in which there was no recorded runoff at the gage site.

3.3 CALIBRATION

Calibration in the sense of comparing the computed runoff with gage data on White Tanks Wash is obviously impossible. The previous discussion in Section 3.2.5 indicates that comparison with a similar watershed is not practical. Lacking this data, the discharges were compared to generalized envelope curves. Four studies were used: one done world-wide by Creager on record floods (ref 21), Arizona record and computed floods by Allan Malvick (ref 40), the data compiled by the USGS on Maricopa County (ref 66) and a compilation of available data for Arizona in ADOT's Hydrology Manual (ref 7). These studies were combined onto a single graph and found to compare extremely well, considering the wide variation in climate involved. Maximum values for individual sub-basins, as well as the flow for the watershed, can be determined directly from this graph for any size area. This concept provides a reasonable standard for evaluating HEC-1 results.

The final data in cfs per square mile versus basin area for each subbasin and final discharge point are plotted on the combined graph on the next page. The project data can be compared with the 100-year peak discharge curves for average southern Arizona watersheds from Malvick's (A) and Eychaner's (B) data and with Creager's curve for C + 17 (C). The results generally compare well with these curves and are certainly within an acceptable range when the variations in the topography and soils are considered. All data points fall under the FCDMC curve (D) developed from the data in Reference 66. This curve ($\text{cfs/sm} = 1900 * \text{area}^{-.5}$) is a straight line on the log plot and can be expected to represent values that are high (and therefore conservative) for basins under one square mile in size.

PEAK DISCHARGE IN CFS/SM

DRAINAGE AREA IN SQUARE MILES

3.4 SPECIAL PROBLEMS/SOLUTIONS

Distributary Flow Areas

The piedmont area east of the Sun Valley Parkway to the base of the White Tank Mountains has several distributary flow areas that received special attention during this study. The reader is referred to USGS Water Resources Investigations Report #91-4171, Flood Hazards of Distributary Flow Areas in Southwestern Arizona (ref 67) and to the Arizona Geological Survey Report, Geologic Mapping of Flood Hazards in Maricopa County - White Tanks Mountains Flood Hazard Maps (ref 9) for more detailed information. Both of these studies specifically include the White Tanks Wash Study Area and the special hydraulic and physiographic characteristics of piedmont slope areas in southwestern Arizona. Distributary flow areas are defined in Reference 67 as areas where flood-flow in a single channel separates into two or more channels and is bounded by the areal extent of major floods. These channels may divide or join several times in the distributary flow area. Floodwater entering the gentler sloping piedmonts from the confining steeper ephemeral streams in the mountains commonly spreads into confined and unconfined distributary channels with a corresponding decrease of velocity and depth. The sediment-laden flow commonly is decreased further by infiltration into sandy channel beds. Because less water and thus less energy is available to transport sediment, deposition occurs in and along the channels. In places, distributary channels may completely fill with sediment resulting in channel avulsions. All the flow from smaller floods may be completely lost to infiltration, depositing its entire sediment load in the distributary flow area. Large floods will remobilize and transport the deposited sediment downstream. The small amount of data available indicates that the avulsion activity in southwestern Arizona is not substantial in relation to engineering time. The runoff and therefore the sediment load delivered during small floods is not substantial and is usually distributed over a significant area of stream bed resulting in deposited material in the tenths of a foot range in the deposition reach. When the infrequency of desert storms is combined with the flushing action of the occasional large storm, it is clear that most distributary flow areas can be considered to be relatively stable for engineering planning.

These distributary flow areas are often more akin to a braided stream than to the classic geological definition of an alluvial fan. If the distributary flow area is bordered by significant interfluves, the stream will migrate only within the area between the interfluves. In the piedmont area of this study, that condition exists at four of the distributary flow areas that have been identified. Each of the distributary flow areas was studied on the topographic maps, the aerial photos and then checked in the field and are discussed individually below. They are identified by the letter of the subbasin involved with M = 36, L = 37, J = 38, and F = 39 as numerically identified in the USGS Distributary Flow report (ref 67).

Area A is in the S½, Sec 21, T3N, R4W at Lat 33°35'02"N, Long 112°39'55"W about midway across the piedmont and 6000 to 7000 feet east of the Parkway. The main stream channel is confined upstream and downstream with two or three branches that separate and recombine in the distributary flow area. There is one small interconnection with subbasin B. The interfluve is lower than the 100 year flood level, but field observation of the ground surface and vegetation indicated that it is relatively stable and likely to pass only small flows in either direction depending upon the relative stages. Since this would tend to decrease the peaks slightly in both streams, the most conservative solution was to analyze them as separated basins.

Area B is near the south border of Sec 21, T3N, R4W at Lat 33°34'53"N, Long 112°40'27"W in the lower half of the piedmont and 3000 to 7000 feet east of the Parkway. The stream divides and recombines numerous times in the upstream portion of this distributary flow area and then into two branches that recombine at the downstream end. Off of the smaller of these two branches, a very small channel leads into subbasin C. Field observation of the vegetation and surface indicated the following: the channel has been stable, it is as likely to become plugged with sediment as to become a substantial branch, and it currently carries an insignificant flow for peak flow calculations.

Area C is near the center of Sec 28, T3N, R4W at Lat 33°34'26"N, Long 112°39'58"W in the lower half of the piedmont and 5000 to 6000 feet east of the Parkway. The stream divides and recombines numerous times in this distributary flow area and remains two branches at the Parkway before recombining downstream. The entire area was included in the single subbasin since it would be difficult to determine the relative flow in each branch during any individual storm. The distributary flow area is included within interfluves.

Area F is near the center of Sec 3, T2N, R4W at Lat 33°32'38"N, Long 112°38'35"W about midway across the piedmont and 6000 to 8000 feet east of the Parkway. The major channels are deeply incised and separated generally by high ridges. The main stream in subbasin F divides and recombines numerous times in the distributary flow area. The field observation found a 4-6 foot high interfluve that appeared to be quite stable and only overtopped during major floods. However it appeared that significant flows may be travelling underground and surfacing downstream in subbasin H. An estimate of the quantity involved would have been well beyond the scope of this project and, although probably decreasing the peak in subbasin F, would be unlikely to increase the peak in subbasin H. Since this ridge represented the only boundary that kept the subbasins separated and they were too large to combine, a method for calculating the cross-over flow was desired that would produce maximum peaks in each channel. The solution used for this study was to allow the flow to stay in subbasin F until it reached the Parkway. The flow across the Parkway was found to be limited by the culvert capacities, and the excess allowed to divert along the parkway into subbasin H. The diversion was larger than our field

estimates for the cross-over flow. This would result in a smaller peak flow in basin H because of a prolonged diversion at the two locations. The peak in basin F3 would probably not be affected since it is controlled by the capacity of the culverts at the Parkway. The selected solution, therefore, meets the objectives of this study.

Area J is in the southwest corner of Sec 10, T2N, R4W at Lat 33°31'35"N, Long 112°39'13"W in the lower half of the piedmont and about 6000 feet east of the Parkway on apparent old fan deposits. The channels are separated generally by low ridges with a few high ones. Although the stream divides and recombines several times in this distributary flow area, it basically stays within subbasin J. There are three very small flood channels that cross the dirt road that generally follows the divide between the basins. These channels appear to be quite stable and the total net flow between basins is insignificant.

Area L is in the corner of Sec 11, 12 and 14, T2N, R4W at Lat 33°31'23"N, Long 112°37'19"W in the upper piedmont and about 14000 to 16000 feet east of the Parkway. The channels are separated generally by low ridges with a few higher ones. The stream divides and recombines numerous times in this distributary flow area and stays separated to the Parkway and the Buckeye Structures. This subbasin is wider than desired so that all of the branch channels would be contained within the selected boundaries for this subbasin. This basin is bounded by similar basins on each side that will force the main stream to remain within the established boundaries. There is a very low probability that there will be any diversion outside of the subbasin in the next 100 years except possibly by man's actions.

Area M has two distributary flow areas. The upper one is in the southeast corner of Sec 14, T2N, R4W at Lat 33°30'52"N, Long 112°37'07"W in the upper piedmont at the base of the mountains and is 14000 to 16000 east of the Parkway. Two main channels about 400 feet apart are separated by low ridges and several stream channels. The channels remain divided until they combine at the northwest corner of hill "Spike". Downstream of this is the lower distributary flow area in the southwest corner of Section 23. The stream divides and remains separated to the Buckeye Structures. This subbasin is also wider than desired so that all of the branch channels are contained within the selected subbasin boundaries. There is a very low probability that there will be any diversion outside of the subbasin in the next 100 years except possibly by man's actions.

Area N is in the northwest corner of Sec 25, T2N, R4W at Lat 33°24'35"N, Long 112°37'27"W as the channel enters the piedmont at the base of the mountains and is about 16000 feet east of the Parkway. The channel is confined by the mountains and hill "Spike" and its branches recombine downstream. This subbasin's boundaries were selected so that all of the branch channels are contained within the subbasin. There is a very low probability that there will be any diversion outside of the subbasin in the next 100 years.

Culvert and Parkway Effects

The Sun Valley Parkway and the culverts crossing under it are a major influence on the flow regime in the study area as discussed above. Each culvert crossing was surveyed in the field and all of its hydraulic parameters determined, including the control weir data for the eastern roadside ditch. This data is tabulated in Book A, Section 2, Sun Valley Parkway Data. Bench mark locations and elevations were extracted from the Sun Valley Parkway As-built drawings to aid the field surveyors in location. Several of these bench marks were surveyed during the culvert survey. Data was also tabulated for the east roadside ditch and culverts from the as-builts. Several discrepancies were found in the data so it is of limited usefulness. Profiles of the ditches and the roadway centerline were digitized from the aerial photos and are included in Book A. This data was used for the diversion flow calculations.

A rating table was computed for each culvert structure and input into HEC-1. Each rating curve was terminated at the center of roadway elevation so that a warning would be given by HEC-1 if the Parkway was overtopped. This condition could then be studied on an individual basis. No occurrence of this was found for the 100-year event. These rating tables allowed the determination of the overflow diversion at each set of culverts when the bank is overtopped and flow is diverted into the roadside ditch. This diversion was added to the flow at the next culvert set and the process continued to the concrete channel at McDowell north of the Buckeye Structures. The only diversion between subbasins in the final data was from basin F to H as discussed on the preceding page. The rating curve data can be found on the following pages.

Storage & Impoundments

The "Tanks" for which the White Tanks Wash and White Tank Mountains are named are natural small rock ponds that are whiter than the surrounding rock because of limestone precipitation as the water evaporates. There are also a few small, old stock tanks in generally poor condition. None of these impoundments store enough water to have any measurable effect on the design flood flows. They are only of interest as sources of water for small numbers of animals between storms.

HEC-1 Warnings

The warnings generated by HEC-1 that remain are technical in nature and do not effect the result. Each warning was checked and the resolution noted in the output.

NOTES:

The equations used herein are from USBPR HDS #5 and are the basis for the charts dated Jan 1963.

The charts are the same as those used by ADOT, FCDMC, COS, ODOT

They are only valid for submerged conditions where $Q/AD^{.5} > 4.0$.

The charts use a culvert slope of 2% and are only within 10% of the correct answers

Other types of culverts can be added by inserting the values of c and y in the table.

ODOT manual has the values on page 26.

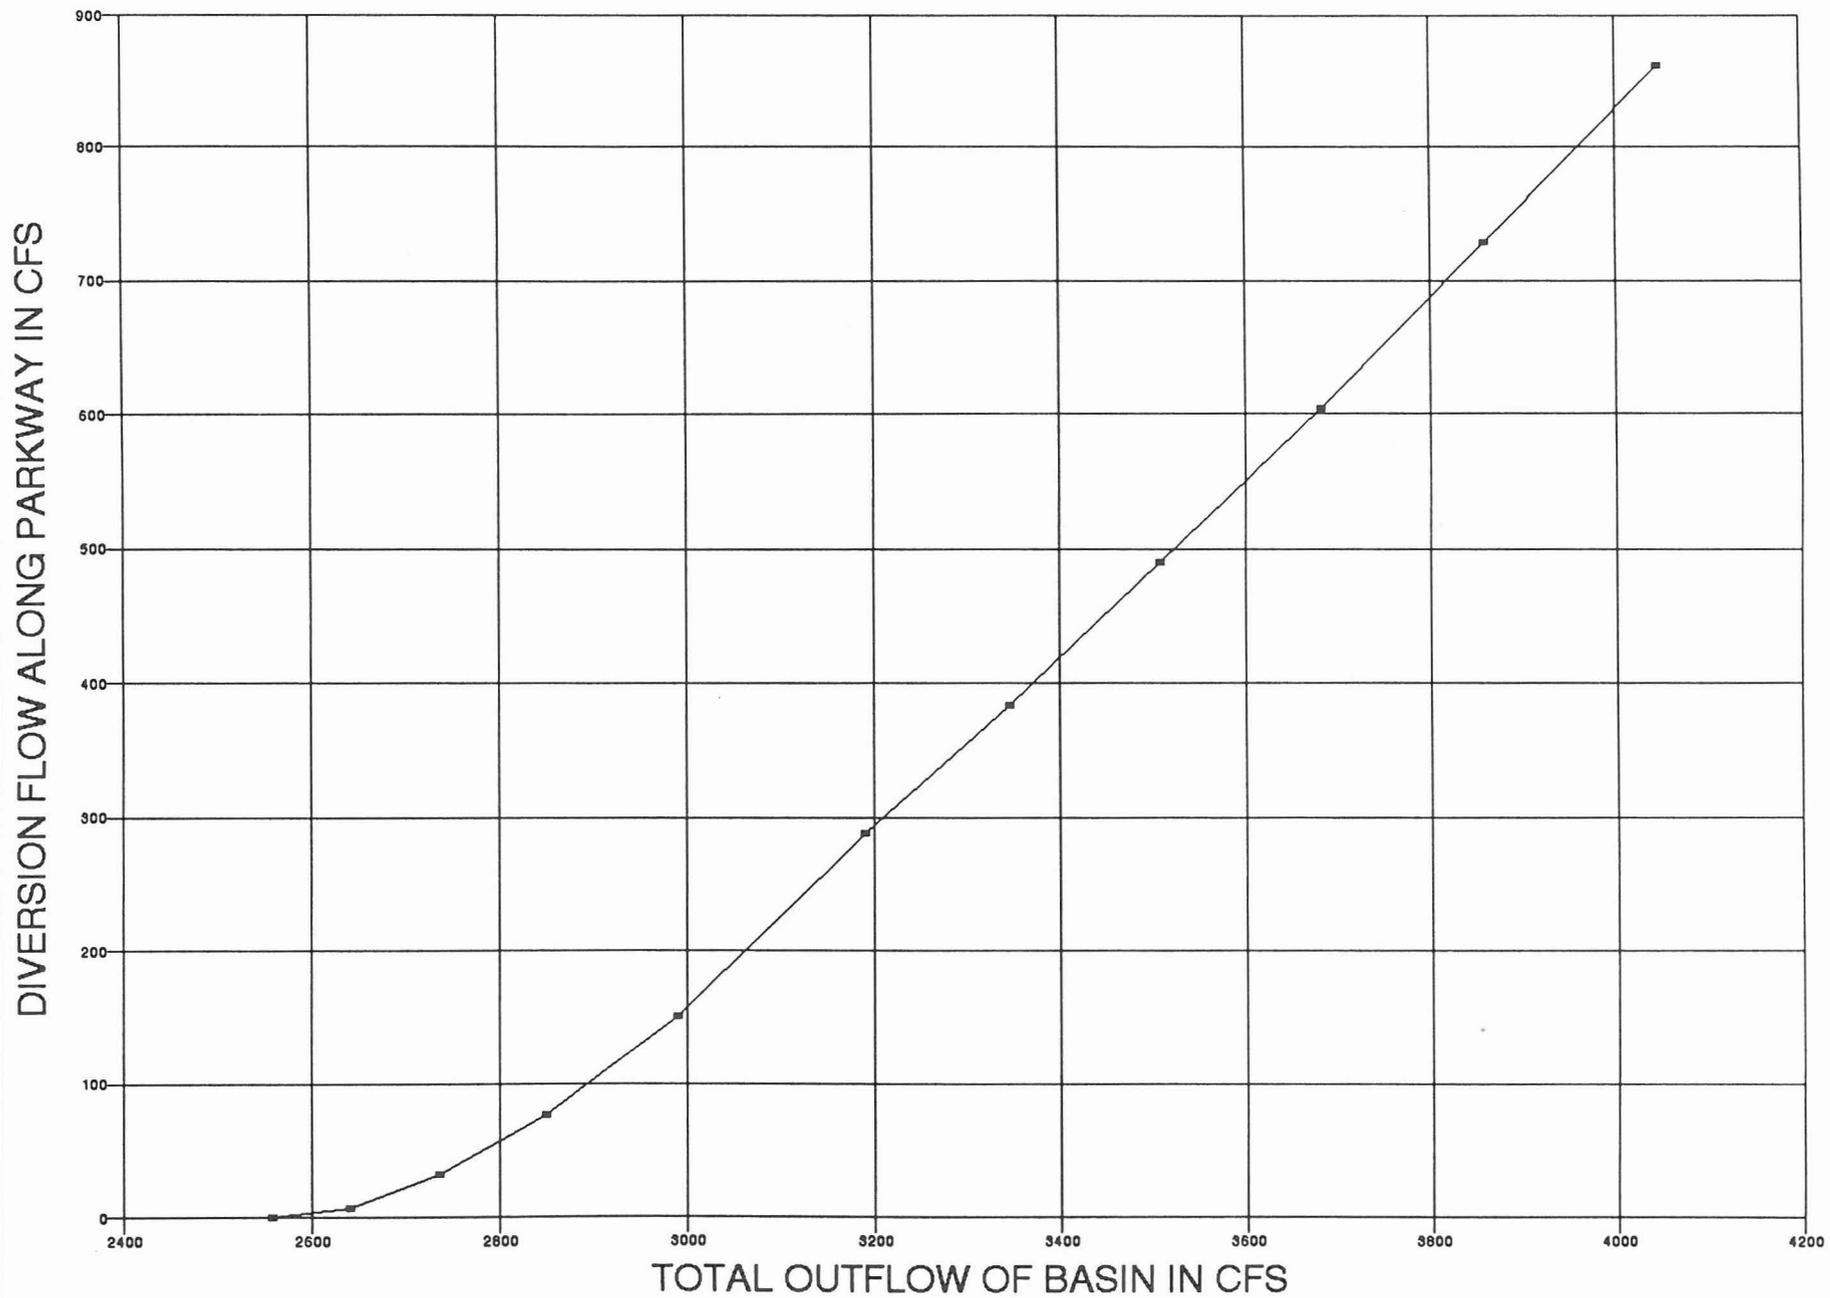

The area of arch culverts is = to circular with a dia = to the (span + rise) /2

The overflow equation is the broad crested weir formula $C = KCLH^{1.5}$

See page 4-96 and 97 of FCDMC Drainage Manual

These equations use a gravel surface with $C = 2.5 + .33(H)^{0.5}$ (see chart B)

BASIN F2

3.5 FINAL RESULTS/COMPUTER RUNS

Results

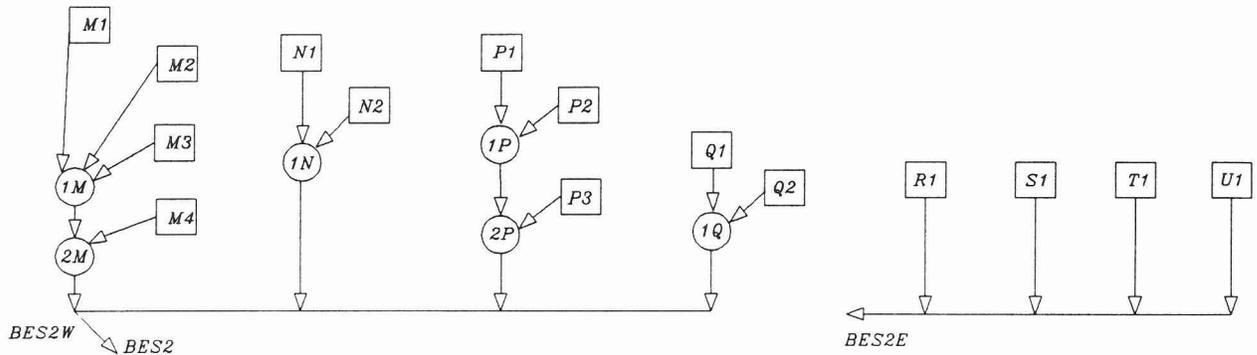

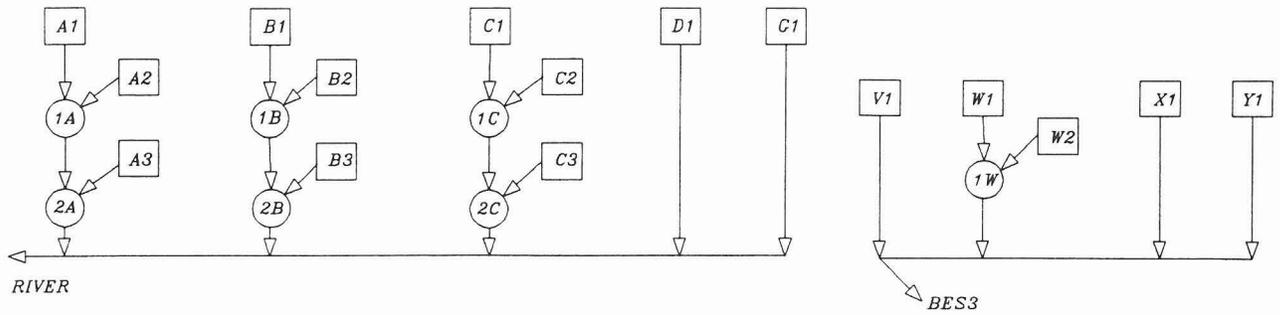

The network diagrams for the HEC-1 basins is on the following page. Peak flow runoff values have been tabulated on the network diagram for both the 6 and 24-hour storms to permit easy comparison and to facilitate understanding of the results. The HEC-1 Runoff Summaries are also included for quick reference. The final results for the 6-hour and 24-hour duration storms are in Sections 3.5.1 and 3.5.2, respectively. The 24 hour storm produced the highest runoff peak flows at all points. The input data and master summary only are included for the 6-hour storm, whereas the full output file for the 24-hour storm is included in the report for reference. Channel transmission losses are not included in either computation because they were found to be less than one percent and therefore insignificant. This is in agreement with studies for similar areas if the multiple use of infiltration factors is accounted for.

Discussion of Results

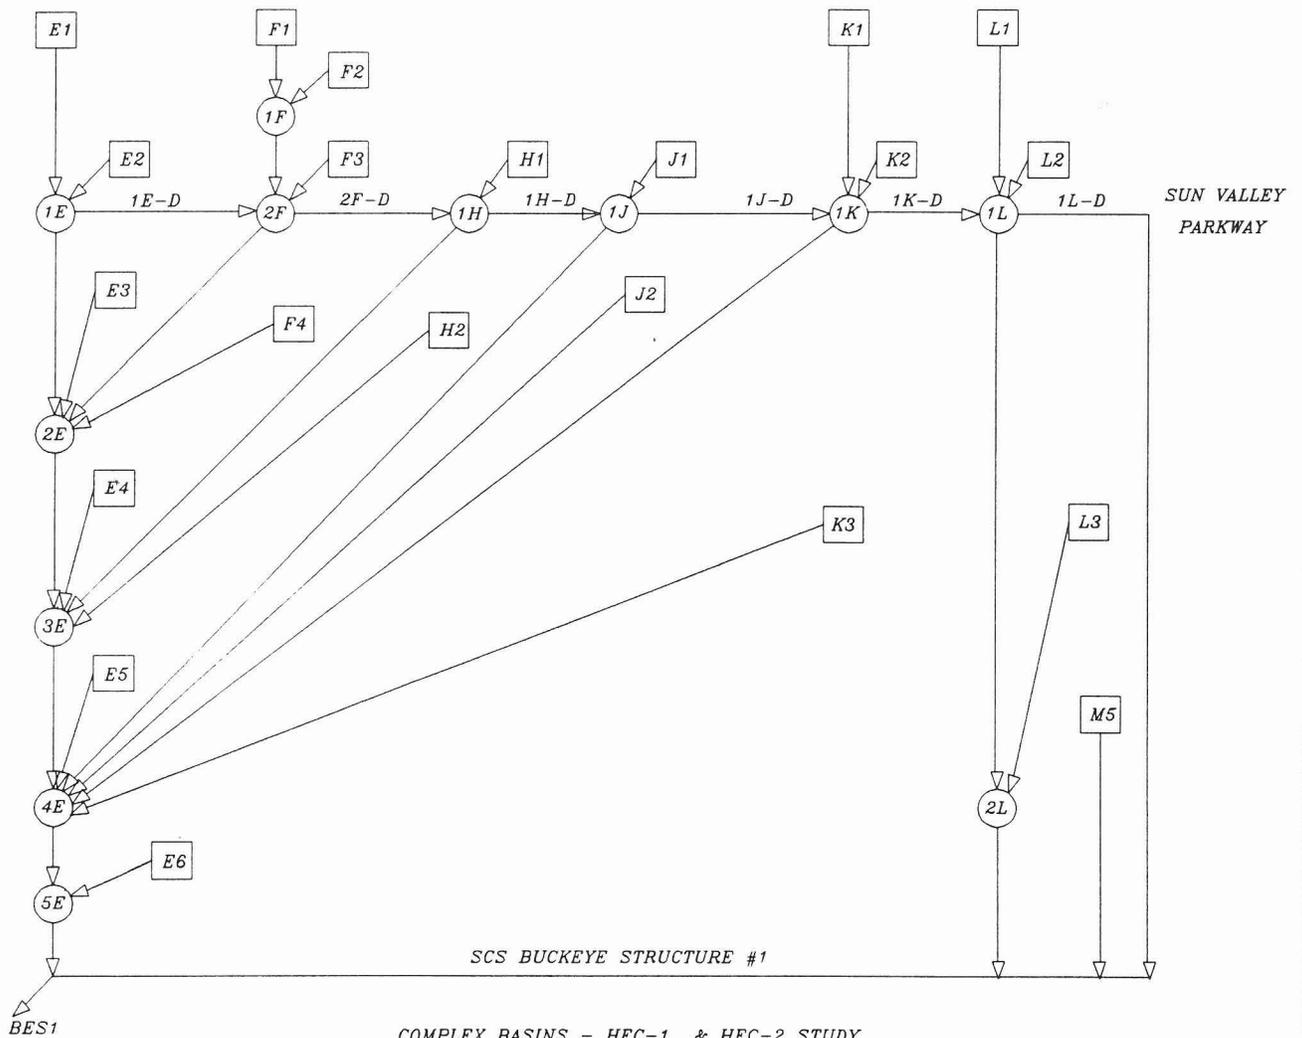

The peak discharges are in the range predicted by the 100-year peak discharge curves for Southern Arizona by Malvick and Eychaner, USGS data for Maricopa County, curves developed for the Arizona Department of Transportation and the C = 17 curve from Creager. They vary slightly from the discharges predicted by the drainage studies performed for the Sun Valley Parkway. However, the culvert sizes selected for that project control the maximum discharge downstream. Therefore, the study area flows predicted in this study are consistent with the drainage design. The major difference is the flow that is predicted for the roadside ditch on the east side of the Parkway from subbasin F to subbasin H.

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
 THE DEFINITION OF -AMSK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
 NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
 DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
 KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

```

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE. THE DEFINITION OF -AMSK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION

NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY, DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION

KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

```

Jim, 1-14-94
 I check all the pages to make sure the numbers were in order and that there were no blank pages - all is well.

Beo

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 9027. TO 38841.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 819. TO 34870.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 1648. TO 73187.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 4912. TO 46081.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 10470. TO 34450.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 5170. TO 30056.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

Handwritten: 2232
OK

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 8180. TO 9641.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 1104. TO 3659.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

Handwritten: 766 up, OK

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 10489. TO 12416.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 6958. TO 12919.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

HYDROGRAPH AT STATION 1N
TRANSPPOSITION AREA 500.0 SQ MI

Table with 5 columns: PEAK FLOW (CFS), TIME (HR), MAXIMUM AVERAGE FLOW (6-HR, 24-HR, 72-HR, 24.92-HR). Values include 1805. CFS at 13.42 HR, with corresponding flow rates in CFS and AC-FT.

CUMULATIVE AREA = 5.59 SQ MI

INTERPOLATED HYDROGRAPH AT 1N

Large data table with 19 columns: DA, MON, HRMN, ORD, FLOW, and 15 columns of interpolated data. It lists hourly flow rates and corresponding coordinates for station 1N.

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 2102. TO 20669.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

992 9. CK
P.

THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)

*** WARNING *** MODIFIED PULS ROUTING MAY BE NUMERICALLY UNSTABLE FOR OUTFLOWS BETWEEN 10369. TO 17029.
 THE ROUTED HYDROGRAPH SHOULD BE EXAMINED FOR OSCILLATIONS OR OUTFLOWS GREATER THAN PEAK INFLOWS.
 THIS CAN BE CORRECTED BY DECREASING THE TIME INTERVAL OR INCREASING STORAGE (USE A LONGER REACH.)
